

NexMile

Choose smarter. Wait less. Arrive on time.

An AI commute assistant for VKU students using bus routes 6 and 13

AI for Everyday Life Hackathon 2026

Đinh Trần Tiến Minh · 23IT162

Nguyễn Thị Yến Nhi · 24DM078

The hardest part is waiting without knowing

A student can arrive at a sheltered stop and still lose control of the trip.

FOUNDER OBSERVATION

Expected around 12:2x

Actual bus at 12:55

In weeks when the bus is used, missed or delayed trips happen roughly twice on average.

The cost is not only the delay. It is the uncertainty between the two times.

Should I keep waiting?

Has the bus already passed?

Could another route be better?

Personal observation, not a city-wide statistic

A narrow first user makes the problem testable

Primary user

VKU students who need a reliable trip to campus

They may not have a personal vehicle available every day.

They use a sheltered stop with seats, so the pain is time uncertainty, not physical discomfort.

They can choose between bus routes 6 and 13.

They care about arriving on time and reducing wasted waiting.

Two different routes, one shared destination

The decision happens at the stop: choose route 6 or route 13.

Existing tools show data. Students need a decision.

The gap is not another map. The gap is confidence at the moment of choice.

CURRENT TOOLS

Where is the bus?

Route maps and live location can help, but still leave the user with a question.

STUDENT'S QUESTION

Should I wait?

Which route is more reliable?
When do I switch?

NEXMILE ADDS

A reliable next action

Compare options, predict the wait and explain what to do next.

We do not replace DanaBus. We add a personal decision layer on top of transport data.

NexMile turns uncertainty into a commute decision

Two moments matter: before leaving home, and while waiting at the stop.

01 BEFORE LEAVING

Choose the commute

Compare bus 6, bus 13 and a personal option.
Use arrival deadline, traffic, weather, cost and parking.
Recommend whether the bus is worth choosing today.

02 WHILE WAITING

Manage the wait

Predict an arrival range and its confidence.
Detect delays, stale GPS or a bus that passed the stop.
Recommend keep waiting, switch routes or use a backup.

The product earns trust by being honest about uncertainty.

AI turns transport signals into a personal recommendation

GPS and sensors are inputs. The value comes from prediction, confidence and action.

One trip, five moments of confidence

The user does not need a perfect prediction. They need a clear next action.

A simple interface for a high-stakes wait

Demo values are illustrative and simulated for the prototype.

Start with two routes, then earn the right to scale

The prototype is small by design. The data model can grow later.

Sensor = data validation layer, not a city-wide dependency.

PILOTABLE

The first version can work with simulated data, then improve through an operator partnership.

A decision layer that makes public transport easier to choose

NexMile does more than track a bus. It helps a student decide, commit and recover when the trip changes.

01

Relevant

Starts with a real student problem on routes 6 and 13.

02

Honest

Recommends the best option, even when that is not the bus.

03

Useful

Turns uncertain waiting into a clear next action.

Choose smarter

Wait less

Arrive on time

NexMile

Nguyễn Thị Yến Nhi · 24DM078

Public transport competes with flexibility

The bus can be a good option and still lose the decision when the wait feels risky.

WHY THE BUS STILL MATTERS

Shared mobility can be a practical choice for students without a personal vehicle.

The problem is not only transport access. It is confidence in the trip.

WHY PEOPLE HESITATE

A personal vehicle feels more flexible when the next bus is uncertain.

Miss one bus and the next choice may feel too far away.

A map can show movement but still leave the user deciding alone.

NexMile lowers the risk of choosing the bus by making uncertainty visible and actionable.

Current options leave the final decision to the student

NexMile sits between raw transport data and the user's personal choice.

OPTION	WHAT IT PROVIDES	WHAT STILL REMAINS
DanaBus	Route and live vehicle information	The user still interprets whether to wait or switch
Static timetable	A planned departure window	It cannot explain road conditions or a late vehicle
Personal vehicle	High flexibility when available	Cost, parking and availability vary by student
NexMile	Prediction, confidence and a next action	A personal decision layer for the commute

The differentiation is not another route map. It is a clear choice under uncertainty.

The model turns signals into a decision

The first prototype can simulate the data. The decision logic stays the same when live data arrives.

INPUTS

- Vehicle GPS
- Stop sensor events
- Route history
- Traffic and weather
- Arrival deadline

MODEL

1 Predict

Arrival-time range

2 Compare

Bus 6, bus 13, backup

3 Detect

Delay or stale signal

DECISION

Recommended route

Route 13

Wait 8–12 min

Keep waiting or switch
with confidence

Success means less wasted time and more confident choices

The pilot should measure behavior and confidence before claiming impact.

WAIT

Time spent waiting per trip

Does the recommended option reduce wasted waiting?

CHOICE

Confident route decisions

Can users decide without checking multiple sources?

ARRIVAL

Late or missed class reports

Does the trip become more predictable for students?

TRUST

Usefulness of the next action

Do users follow the recommendation when data is uncertain?

We will not claim improvement before the pilot measures it.

Start narrow, prove trust, then scale

NexMile begins with the routes and decisions the team understands best.

Prototype

Simulated GPS and sensor data
Clickable demo for VKU students

Pilot

Routes 6 and 13
3–5 stops near VKU

Scale

Operator data partnership
More routes and user groups

A small, honest product can make public transport easier to choose.
